Q: Why did the TARDIS get so late in the first episode of the new season? In the opening episode of the new Doctor Who series, The Eleventh Hour, we see the Doctor arrive in the TARDIS only to find that the TARDIS is later than the other one. For example: Why didn't the Doctor arrive earlier? A: As far as the Doctor's Time-Line is concerned: If the Doctor landed at any time during his last trip through history he might have arrived before the present day. If the Doctor landed on a different part of Earth then he would still have to travel the correct amount of time to get to the same time as his last trip around Earth. And to answer your question... The Doctor could always have been a little earlier. As he approached the first departure point he was turned away by that Time Lord. So he had to turn around and come back a few minutes early. This is the same for the second departure point, except the Doctor didn't turn back until he reached the same time as before. He had to wait until the previous departure point was fixed. So the Doctor only had to turn around when he reached the next departure point. The Doctor can go anywhere in the universe, so he can visit any time or place, but since he can't visit himself at the same time as his previous visit, he can't visit the same time twice. Now this doesn't mean that in real time he can't be any earlier than he is when he travels to a point in time, only that the Time-Line won't let him visit it twice. In vitro changes of myocardial performance index during postnatal development of rat. To determine the effect of postnatal development on myocardial performance index (MPI), the ratio of time-averaged velocity of myocardial systolic contraction to myocardial relaxation (average velocity of left ventricular systolic contraction [S] to average velocity of early diastolic filling [E] of the left ventricle), we examined the hemodynamic status of rat hearts in vitro under various loading conditions by using the LV pressure-volume system. During the in vitro perfusion with Krebs-Henseleit solution at a constant flow, the baseline MPI was  $0.82 \pm 0.02$  (mean  $\pm$  SD) and remained constant during the 82157476af
